

RICE-FLOUR HYDROLYSATES FAT SUBSTITUTE

THE PRESENT INVENTION CLAIMED IS

5

1. A food-making process, comprising the steps of:
starting with a rice flour ingredient;
adding an enzyme to the rice flour ingredient; and
extruding a slurry including said rice flour

10 ingredient and said enzyme to obtain a hydrolysis of rice
flour;

wherein, a product is produced with a water content
of 5%-25%, by weight.

15

2. The food-making process of claim 1, further
comprising the step of:

substituting said product for a fat ingredient in a
final food product.

20

3. The food-making process of claim 1, further
comprising the step of:

using said product instead of shortening in a final
food product.

25

4. The food-making process of claim 1, wherein:

the step of extruding promotes a short-time
conversion of said rice flour in the presence of said enzyme.

30

5. The food-making process of claim 1, wherein:

the step of extruding includes a hydrolysis process
that produces simple sugars, and said product has a water
activity low enough to mimic the texture of fat that will not
sustain significant microbiological growth.

6. The food-making process of claim 1, further comprising the step of:

blending rice syrup with said rice flour in said slurry before the step of extruding and providing for an enzymatic reaction.

7. The food-making process of claim 1, further comprising the step of:

blending a sweetener with said rice flour in said slurry before the step of extruding and providing for an enzymatic reaction.

8. The food-making process of claim 1, wherein:

the step of extruding is such that said product appears like shortening, and is a combination of water, flours, simple sugars, and complex carbohydrates that have substantially less calories than fat.

9. The food-making process of claim 1, wherein:

the step of extruding is such that said product includes proteins that can act as emulsifiers.

10. The food-making process of claim 1, wherein:

the step of extruding does not include the use of an emulsifier in said slurry.

11. The food-making process of claim 1, wherein:

the step of extruding is such that said product has a bland, neutral taste.

12. The food-making process of claim 1, further comprising the step of:

extruding a second time to inactivate said enzymes and thereby adjust the pH of said product.

13. The food-making process of claim 1, wherein:
the step of extruding is extended over 3-10
seconds.

5

14. The food-making process of claim 1, wherein:
the step of extruding is conducted between a
temperature of 35°C to 60°C.

10

15. A system for making a fat substitute for use in
foods, comprising:

a rice flour ingredient;

an enzyme which is added to the rice flour
ingredient; and

15

means for extruding a slurry including the rice
flour ingredient and the enzyme to obtain a hydrolysis of
rice flour;

wherein, a fat substitute with a water content of
5%-25%, by weight results.

20

16. The system of claim 15, wherein:
the means for extruding promotes during operation a
short-time conversion of said rice flour in the presence of
said enzyme.

25

17. The system of claim 15, further comprising:
a rice syrup that is blended in with the rice flour
in said slurry before extruding, such that an enzymatic
reaction results after extruding.

30

18. The system of claim 15, wherein:
the means for extruding extrudes said slurry over a
period of 3-10 seconds.
